

1.2 Who in the world has water?

The following sources are choropleth maps. These are colour coded maps, where darker shades represent more of something (such as precipitation/rain in Source A). Assess the maps and answer the questions.

Source A: Annual precipitation, 2024

Total annual precipitation — rain and snow — calculated as the sum of daily averages, reported as the depth of water falling to Earth's surface, excluding fog and dew.

<https://ourworldindata.org/grapher/average-precipitation-per-year?overlay=download-avis>

Source B: Renewable freshwater resources available per person 2021

Renewable internal freshwater resources refers to the quantity of internal freshwater from inflowing river basins and recharging groundwater aquifers. This is measured in cubic meters per person per year.

SOURCE A: Questions

1. How does latitude influence rainfall patterns?

2. Choose one region. Explain how its rainfall pattern might influence the availability of water resources there and predict why the rainfall patterns are the way they are.

3. Explain how precipitation patterns could shape broader environmental conditions (for example, vegetation or river systems).

Section B: Questions

5. Describe the global distribution of renewable freshwater per person.

6. Compare a region with abundant rainfall to one with abundant freshwater per person. What is similar or different?

7. Suggest one reason why freshwater per person may be low even in areas with high rainfall.
